Schema and checks 2

Verdict 2

Problem statement

The plan fixes the protocol: every new experiment must contain (1) an exact mathematical statement, (2) the list of premises, (3) a numerical result with reproducible code, (4) control models and a sensitivity analysis, (5) the list of what the result does NOT prove. The cautionary examples matter: p_KS = 0.27 does not “prove GUE”, and ‖H−H†‖ < 1e-14 for a finite matrix does not prove self-adjointness of an infinite-dimensional operator.

The campaign implements this protocol as executable infrastructure: a claim-JSON schema, an auditor, and 15 claim files — one per campaign of the series.

Schema and checks

A1 — form: all five parts present and non-empty. A2 — status hygiene: the status vocabulary (proven/measured/conjecture/refuted); the “proven” status requires at least one passed control AND a non-empty list of non-implications; p-values are banned as justification of “proven”. A3 — coverage: every verdict data/v*_verdict.json must have a claim file.

The auditor runs in the package tests: an audit regression is a release stopper, as in the reference.

Table 1. Status registry of the 19 campaigns

Status	Campaigns
proven	V4 (Th1), V7 (Th6), V8 (Th2), V9 (Th5), V12 (Th3), V15 (Th4)
measured	V1, V2, V3, V5, V6, V10, V11, V13, V14, V16, V17, V18, V19
conjecture / refuted	— (conjectures live in the V13 DAG with status assumed)

Verdict

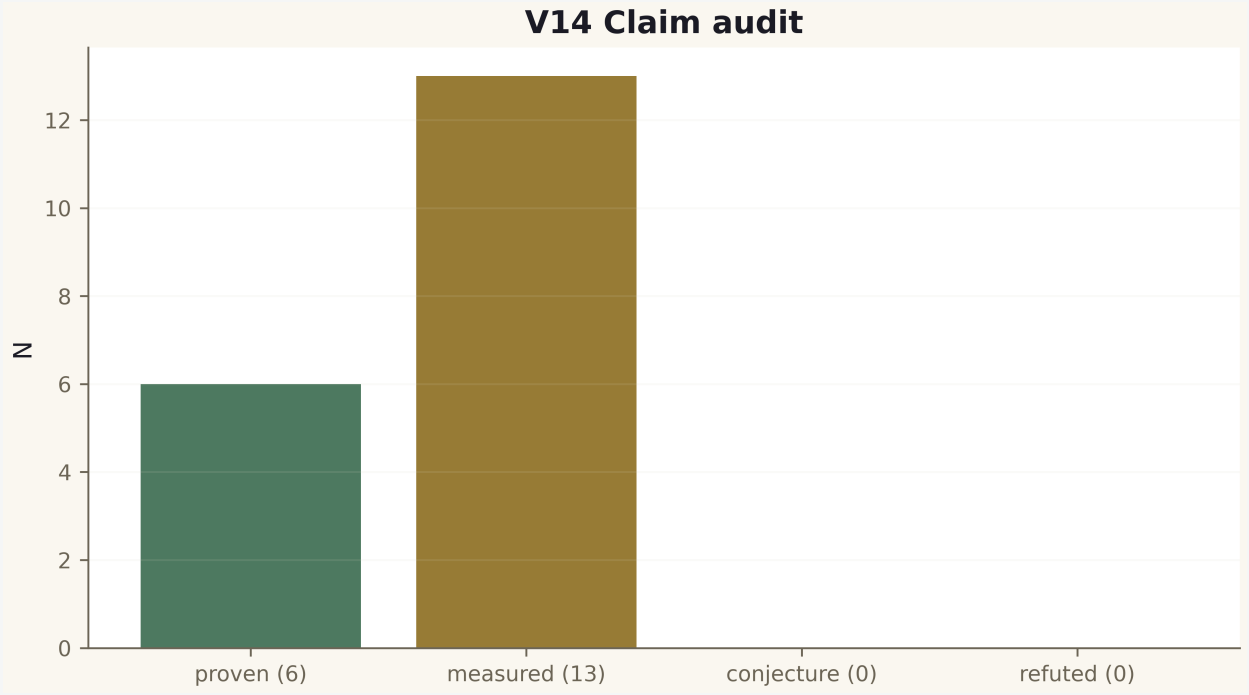

Fig. 1. Campaign V14 data (600 dpi, file figures_hires).

The audit passes: 19/19 claims per the schema (V19 included in v1.1.0), full coverage, status hygiene observed. Every public statement of the package is traced to a computation, a control and a list of non-implications.
